Master company, product, website, and operating document

Version: 1.0 **Updated:** September 2026 **Status:** Current working system **Primary promise:** Build AI for production.

1. Executive summary

CuriousDevs is an AI engineering and intelligent-systems studio. We research, engineer, and build technology for difficult real-world problems.

The company works across a connected continuum:

Research -> Engineering -> Systems -> Products -> Real-world impact

The near-term focus is production AI engineering: building AI-native products, improving existing AI systems, and creating the evaluation, security, deployment, and operating discipline required for reliable production use.

The longer-term direction extends toward intelligent systems, robotics, edge intelligence, advanced hardware, and DeepTech. Future capability should be presented as a direction under development, not as an unsupported current claim.

2. Positioning

Category

AI engineering and intelligent-systems studio.

One-line description

CuriousDevs helps teams build, fix, and scale serious AI systems for production.

What we believe

A model call is not a production system. A dependable system also needs:

- Clear scope, ownership, and acceptance criteria.
- Grounded data, retrieval quality, and reliable context.
- Evaluation sets, regression checks, and measurable baselines.
- Security, permissions, guardrails, and data-flow discipline.
- Latency, cost, observability, deployment, and incident readiness.
- Documentation, handover, and a team that can operate the result.

What we are not

- A generic software outsourcing shop.
- A prompt-only consultancy.

- A slide-deck AI consultancy.
- A prototype-only studio.
- A hype-driven AI brand.
- A DeepTech company by claim alone.

3. Mission, vision, and standard

Mission

Make serious AI systems buildable, measurable, secure, and operable.

Vision

A world where intelligence moves from impressive prototype to trusted production capability, and from software into systems that can perceive, decide, and act responsibly in the real world.

North Star

Every serious intelligent system should have a measurable baseline, a clear owner, and an operating path its team can trust.

Operating standard

Baseline before intervention. Comparable evidence before claims.

4. What CuriousDevs does

Build

Design and engineer AI-native products and intelligent workflows:

- RAG applications, enterprise search, and knowledge copilots.
- AI agents, tools, APIs, memory, permissions, and workflow automation.
- Planner, executor, reviewer, and multi-agent orchestration.
- Multimodal product features and embedded intelligence.
- Backend systems, integrations, data pipelines, and application logic.
- Evaluation, security, deployment, documentation, and handover.

Audit / Assessment

Create a clear view of an existing AI system before the next investment:

- Retrieval, grounding, answer quality, and hallucination review.
- Agent trajectory, tool-use, edge-case, and regression review.
- Prompt injection, access control, data leakage, and guardrail review.
- Latency, token usage, cost, reliability, and infrastructure review.

- Scorecard, failure map, priority order, and decision-ready next step.

Fix

Diagnose root causes and improve reliability:

- Retrieval precision and recall.
- Agent QA and unsafe trajectories.
- Accuracy, latency, cost, and workflow failures.
- MCP, tool permissions, integrations, and data-flow risks.
- Before-and-after evidence for every meaningful change.

Scale

Productionize AI systems so teams can operate them:

- Cloud, private, and VPC deployment.
- Docker, Kubernetes, CI/CD, and release controls.
- Model routing, semantic caching, token attribution, and cost policies.
- Logs, traces, metrics, alerts, and incident runbooks.
- Security hardening, resilience, fallback behavior, and access governance.
- Documentation, training, QA, and ongoing engineering support.

5. Technology areas

These are four connected areas inside one intelligent-systems thesis.

01. AI Engineering

Building intelligent software that works in production.

LLMs, RAG, agents, automation, multimodal AI, evaluation, security, reliability, observability, infrastructure, and deployment.

Core question: how do we turn a model or workflow into a reliable, measurable system?

02. Intelligent Systems

Moving intelligence closer to where perception and decisions happen.

Computer vision, edge AI, embedded intelligence, sensors, real-time inference, decision systems, and on-device AI.

Core question: what should happen locally, within real latency, power, connectivity, and safety limits?

03. Robotics

Extending intelligence into machines that perceive and act.

Perception, planning, control, navigation, manipulation, autonomy, physical AI, and machine intelligence.

Core question: how do perception, planning, and control close the loop on a physical machine?

04. DeepTech

Exploring deeper technologies that expand what intelligent systems can do.

AI hardware, accelerators, specialized compute, AI-native devices, advanced sensors, intelligent machines, neurotechnology / BCI, and advanced computing.

DeepTech is the umbrella for the deeper physical and computational layers. Robotics, physical AI, autonomy, and embedded systems can be represented within this direction where appropriate.

6. Product directions

Noema

Intelligence that understands.

Noema is the intelligence layer: a multimodal foundation for perception, representation, reasoning, planning, and action.

It is designed to connect:

Text / image / audio / sensor context -> perception -> understanding -> reasoning -> planning -> action

Noema focuses on grounded context, auditable tool use, uncertainty-aware decisions, measurable evaluation, and real-world task outcomes.

Key questions:

- What representation best connects language to the state of the world?
- How should uncertainty change a model's plan or request for help?
- Which evaluations demonstrate reliable understanding beyond a polished demo?

Soma

Intelligence, embodied.

Soma is the embodiment layer and humanoid robotics direction: a physical platform with vision, depth, touch, balance, edge compute, dexterous control, and safe motion.

It is designed around:

Sensors -> perception -> understand -> plan -> move -> act -> adapt

Soma focuses on low-latency edge inference, perception-to-action budgets, hard safety boundaries, manipulation, autonomy, episode capture, and telemetry.

Key questions:

- How should a humanoid degrade safely when perception is uncertain?
- Which skills transfer across homes, workplaces, and changing objects?
- What latency budget is required from camera to hand?

Noema x Soma

Noema helps systems understand. Soma gives that intelligence a body capable of acting in the physical world.

The relationship is explicit:

- Noema can propose.
- Soma can execute.
- Safety limits, permissions, fallbacks, and human override remain outside the unconstrained model path.
- Every deployment should produce evidence that improves the next iteration.

7. Research-to-product continuum

CuriousDevs uses a continuous operating model:

1. **Research** - explore the question and the possible solution space. 2. **Prototype** - validate the core loop and the riskiest assumption. 3. **Engineer** - turn the loop into a reliable, secure, testable system. 4. **Deploy** - put it into the context where value is created. 5. **Operate and evolve** - monitor, learn, improve, and document the next version.

Each stage should leave evidence for the next stage. A handoff is not complete until the next owner understands the system, its limits, and its operating path.

8. Brand and design system

Voice

CuriousDevs should sound:

- Precise, calm, and technically credible.
- Curious without sounding speculative.
- Direct about constraints, uncertainty, and evidence.
- Ambitious in direction but honest about what exists today.
- Human and collaborative, not corporate or hype-heavy.

Visual language

- Dark navy technical canvas.
- Warm orange for signal, action, and emphasis.
- Cool blue for intelligence, data, and system flow.
- Fine grid fields, restrained glow, thin technical lines, and compact labels.
- Diagrams that explain a real relationship, not decorative AI imagery.
- Realistic system logic: inputs, representations, decisions, control, actuation, and feedback.

Core visual assets

- Noema multimodal intelligence flow.
- Soma humanoid perception-to-actuation diagram.
- Technology-area diagrams for AI Engineering, Intelligent Systems, Robotics, and DeepTech.
- Research-to-product timeline.
- Noema x Soma architecture and safety boundary.
- CuriousDevs LinkedIn cover banner.

9. Website map

Page	Route	Role
Home	/	Company story, promise, technology thesis, products, and CTA
Technology	/technology	Four technology areas and related system flows
Noema	/technology/noema	Intelligence-layer product page
Soma	/technology/soma	Embodied-intelligence and humanoid robotics page
Systems	/systems	Intelligent system architectures and flows
Work	/work	Selected research, engineering, and product work
Research	/research	Research areas and open questions
Company	/company	About, principles, core story, and direction
Product	/product	Build, Audit, Fix, and Scale service model
Contact	/contact	Contact form and email fallback
Careers	/careers	Current hiring and opportunities

FAQ	/faq	Common questions

10. Contact and communication

Primary contact

hello@curiousdevs.com

LinkedIn

<https://www.linkedin.com/company/curiousdevs>

Contact form behavior

The website contact form:

- Validates the visitor's name and email.
- Captures company, stage, problem, and context.
- Sends the message through the server-side SMTP action.
- Delivers to CONTACT_EMAIL.
- Uses the visitor's email as Reply-To.
- Shows a direct mailto: fallback when sending fails.

Never place SMTP credentials in client-side code or commit .env.local.

11. Technical repository notes

Stack

- React 19.
- TanStack Start and file-based routing.
- Vite 8.
- Tailwind CSS v4.
- Radix UI primitives.
- Lucide icons.
- Nitro with the cloudflare-module preset.
- Nodemailer for server-side email.

Important locations

src/content/site.ts	Core company and technology content
src/components/landing/	Shared page sections
src/components/landing/visuals/	SVG system diagrams
src/components/landing/product-data.ts	Build / Audit / Fix / Scale data
src/components/landing/LayerPage.tsx	Noema and Soma product-page shell
src/components/landing/CompanyBannerVisual.tsx	Company page banner visual
src/lib/actions.ts	Server actions and form handling

src/routes/	File-based website routes
public/brand/	Brand marks and upload-ready assets
output/pdf/	Generated product PDF artifacts

Local development

```
bun install
bun run dev
```

The local site runs on port 8080.

Validation

```
bun run lint
bun run build
```

For visual work, check desktop and mobile layouts on the home, technology, Noema, Soma, company, work, and contact pages.

12. Decision rules

When adding new company or product content:

1. State whether it is current capability, active product direction, or future research. 2. Tie every diagram to a real system relationship. 3. Avoid invented customers, deployments, performance numbers, or research results. 4. Prefer measurable engineering language over generic AI marketing. 5. Keep the four technology areas connected rather than presenting them as unrelated businesses. 6. Preserve accessibility, responsive behavior, and a clear fallback for every important action. 7. Keep the website, README, PDF, social banner, and product pages consistent with this document.

13. Current artifacts

- README.md - repository setup and developer guide.
- output/pdf/CuriousDevs_Product_Overview_2026.pdf - six-page customer-facing product overview.
- public/brand/curiousdevs-linkedin-cover-1584x396.png - upload-ready LinkedIn cover banner.

This master document is the source of truth for the current CuriousDevs story, product direction, website structure, and design intent.
